Performance and Egg Quality Characteristics of Pullets Fed Activated Sheabutter Charcoal Based Diets

B.A. Ayanwale', A.G. Lanko² and Y.S. Kudu³ ^{1,3}Department of Animal Production, Federal University of Technology, P.M.B 65, Minna, Niger State, Nigeria ²Niger State Ministry of Agriculture, Veterinary Services Division, Bosso, Minna, Nigeria

Abstract: An experiment was conducted to investigate the growth performance, nutrient utilization, egg quality characteristics and cost-benefit values of feeding different levels activated sheabutter tree charcoal to laying pullets. Five experimental diets supplemented with activated sheabutter charcoal were formulated to contain pullets. Five experimental diets supplemented with activated sheabutter charcoal were formulated to contain pullets. Five experimental diets supplemented with activated sheabutter charcoal were formulated to contain pullets. Five experimental diets supplemented with activated sheabutter charcoal were formulated to contain pullets. Five experimental diets supplemented with activated sheabutter charcoal pullets were used for 0.0 (control), 10.0, 20.0, 30.0 and 40.0% levels of the charcoal. A total of 150 day-old pullets were used for the study and were fed the diets till they were 22 weeks of age. The results showed no beneficial effect of the study and were fed the diets till they were 22 weeks of age as there were no significant (p>0.05) feeding activated sheabutter charcoal to pullets up to 15 weeks of age as there were no significant (p>0.05) feeding activated sheabutter charcoal to pullets up to 15 weeks of age. At the laying stage, activated sheabutter charcoal significantly (p<0.05) improved egg weight from (48 \pm 3.01) in the control to (54.86 \pm 3.01) in 40.0% charcoal level. Percent cracked eggs also reduced significantly (p<0.05) from 15.33% (control) to 0.20% in 40.0% activated sheabutter charcoal level. No significant (p>0.05) effect of activated sheabutter charcoal was observed on the internal egg quality parameters measured. The pullets fed activated charcoal had higher economic returns than the control. The results were attributed to increased mineral intake and utilization enhanced by charcoal supplementation and also improved absorption capacity of charcoal for dietary fat.

Key words: Sheabutter tree charcoal, cost-benefit, egg quality

Introduction

The term charcoal generally refers to the carbonaceous residue of wood, cellulose, coconut shells or various industrial wastes left after heating organic matter in absence of oxygen (Kutlu *et al.*, 2000). It is a fine, odourless, tasteless black powder and adsorbent of many toxins, gases, drugs, fat and fat-soluble substances. Kutlu *et al.* (2000) stated that the adsorptive capacity of charcoal is increased by treating with temperatures ranging from 500°C to 900°C and with various substances. The product of such treatment, according to Osol (1975) is known as "activated charcoal".

Activated charcoal is widely used in adsorption therapy as a non-digestible carrier which is one of the important methods of preventing ingested toxicants from being formed in gastrointestinal tract (Varma, 1986; Mulyanto,

(Murdiat et al., 1991). Kutlu et al. (2000) however, stated that activated charcoal should be considered as a potential sequestering agent for some toxins and antinutritional metabolites which are detrimental to animals. The authors, however worked on "inactivated charcoal", a situation which suggests that the effect of activated charcoal on the performance of birds, carcass production and parameters, quality egg egg characteristics have not been examined. This study was therefore carried out to examine the growth, nutrient utilization, egg quality characteristics and cost/ benefit values of pullets fed activated sheabutter charcoal in the diets.

Materials and Methods

A total of 150 day-old Isa brown pullet chicks were used for this study. They were randomly distributed into 5 treatment groups in three replicates. Initial average body weight was recorded (66.67g). The brooding temperatures were between 32-35°C for the first 4 weeks of age in accordance with the recommendation of Oluyemi and Roberts (1979) for birds raised in hot humid tropical environment.

1988; McLennan and Amos, 1989, McKenzie, 1991; Jindal et al., 1994; Jindal and MahiPal, 1999; Kutlu et al., 2000). Various other functions of activiated charcoal include, control of lactic acid concentration, maintenance of pH level and microfloria in the steer rumen during and after acute rumen over loading with barley (Hoshi et al., 1991), control of pathogenic bacteria (Almagambetov et al., 1992; Nikoleava et al., 1994) and control of complexes formation with phonelics in the gastrointestinal tract so as to prevent hydrosable tannin interfering with enzyme function and protein digestion

Experimental diets

Sheabutter charcoal preparation: Sheabutter charcoal used in this study as a feed ingredient or as a supplement was taken after activation in a mud bakery

furnace and ground to pass through 0.02mm sieve. The ground charcoal was then mixed thoroughly with other feed ingredients (Table 1). Five different diets containing 0.0 (control) 10.0, 20.0, 30.0 and 40.0% ground sheabuter charcoal were formulated for chicks, growers' and layers' stages (Table 1).

Table 1: Composition of experimental diata

Growth measurements: The effects of dietary sheabutter charcoal growth at chicks and growers phases were assessed. The pullets were raised on deep litter system in an open sided house. The relative humidity in the house was between 60-70%. The open sides of the house were covered with polythene sheets during brooding. Brooding was stopped at 4 weeks of age. Feed and water were given ad - libitum. Light was provided 24 hrs each day except when there was occasional power outage, during which heat supply was augmented with heat from kerosene stove or coal pots. Chicks diets were fed till the end of 8 weeks while growers diets were fed between 8-15weeks. The pullets were housed in a randomized complete block (RCB) design. Data were collected on average body weight, weight gain, feed intake, feed/gain ratio and protein efficiency ratio at chicks and pullets stages.

respectively. Both external and internal egg quality characteristics were evaluated. Each egg was weighed to the nearest 0.0lg using a sensitive top loading electric weighing balance. Egg Length and width were measured with Vernier sliding calipers and the results were used to compute egg shape index, that is, egg width over egg length. Each egg was broken on a petridish. Egg shells were collected and allowed to dry after which egg membranes were removed. The shell thickness was then measured with micrometer screw gauge. The measurements were taken from the top (pointed part) bottom (round part) and middle of the eggs and the average found as described by Ayanwale and Gado (2001).

The internal egg quality measured included egg albumen and yolk heights using tripod micrometer. The yolk diameter was taken as the maximum cross sectional diameter of the yolk using spherometer, read in millimeters. Yolk was carefully separated from the albumen with yolk cups. The yolk was carefully rolled on a damp paper to remove any adhering albumen prior to weighing. Haugh unit was then calculated as:

Laying stage: The same management procedures used for the growers" stage were adopted at this stage. Pullets were given supplements of sheabutter charcoal in their diets, at 0.0, 10.0, 20.0, 30.0 and 40.0% levels (Hu) = 100 log (H + $7.57 - 1.7^{W 0.37}$) where

Chemical analysis: The different diets were oven-dried at 80°C until constant weights were obtained, after which they were stored in air-tight bottles for chemical analysis. The chemical composition of the diets was determined by A.O.A.C. (2000) methods.

Results and Discussion

Table	1	shows	the	gross	composition	of	the

Data analysis: The various data collected on egg quality parameters were statistically analyzed using completely randomized design (CRD) according to Gomez and Gomez (1984). Mean separation was done where significant differences exist using Duncan (1955) producers.

experimental chicks, growers' and layers' diets while Tables 2 and 3 indicate the proximate composition of the activated shea butter charcoal and the experimental diets respectively. The results of the growth performance (Table 4) shows that the dietary sheabutter charcoal had no significant (p>0.05) effect on the growth performance characteristics measured at the 3 stages. This is in agreement with Kutlu et al. (2000). Table 5 shows that activated shea butter charcoal at 40.0 % level significantly (p<0.05) increased egg weight

and reduced percent cracked eggs compared to the control and 10.0% inclusion level and similarly affected egg shape index. There appeared to be a high and negative correlation between the proportion of cracked eggs and weights such that as the egg weight increased the proportion of cracked eggs decreased. These results were attributed to the better mineral availability or utilization enhanced by the higher level of activated charcoal. Kutlu et al. (2000) attributed the reduction in cracked eggs by charcoal inclusion to increase in shell strength, improved mineral intake from charcoal, and absorption capacity of charcoal for dietary fat and its excretion. The authors stated that the major components of charcoal are calcium, potassium and magnesium. Sheabutter charcoal inclusion had no significant (p> 0.05) effect on the internal egg quality characteristics measured (Table 6). This agrees with the findings of Kutlu et al. (2000).

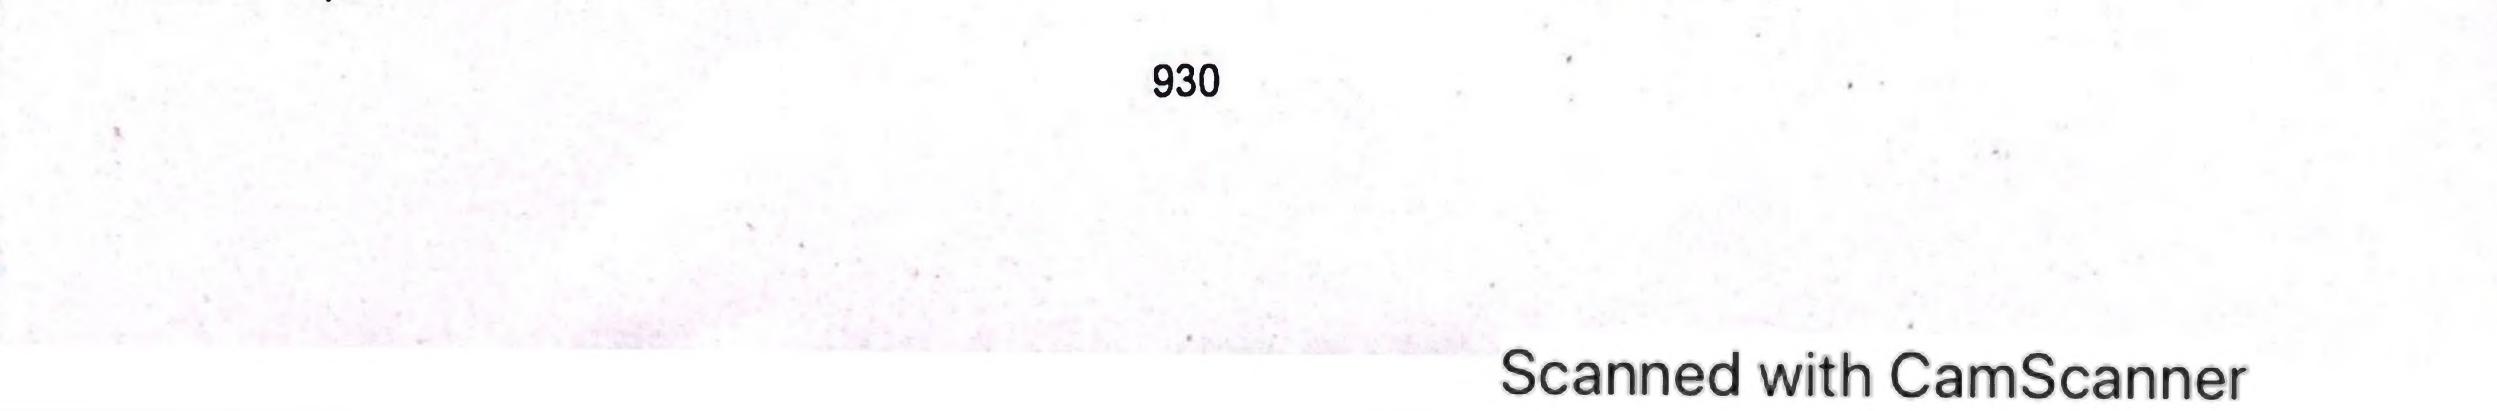

age. However, feeding of activated sheabutter charcoal at the laying stage significantly (p< 0.05) improved egg weight and reduced the proportion of cracked eggs particularly at 40% inclusion level. No significant (p>0.05) effect of sheabutter charcoal inclusion in the diets was observed on the internal egg quality characteristics. The results were attributed to improved mineral intake and utilization enhanced by charcoal inclusion, and improved absorption capacity of charcoal for dietary fat and its excretion. Pullets fed activated charcoal had higher economic returns than the pullets fed the control diet.

The results of the cost / benefit analysis shown in Table 7 shows that the highest income was from the pullets fed 40% activated charcoal and the least was from the pullets fed the control diet.

Conclusion: The results of this study indicated that there is no beneficial effect of feeding activated sheabutter charcoal to pullet chicks and growers up to 15 weeks of
